

Phase 13: Equation Dependency Audit

The equation catalog matches every active labeled baseline equation to its source file, line and semantic dependency row. Conditional on a candidate capacity price, the evaluation graph is acyclic. The one intentional feedback is resolved by the scalar market-clearing condition:

$$p_m \longrightarrow (W_E, r_i^*, \Omega_i, x_i^*, D_m), \quad p_m \longrightarrow S_m, \quad D_m(p_m) - S_m(p_m) = 0.$$

The endogenous root feeds back to all price-conditioned choices. Neither extension-only equations nor unapproved later modules enter this graph.
